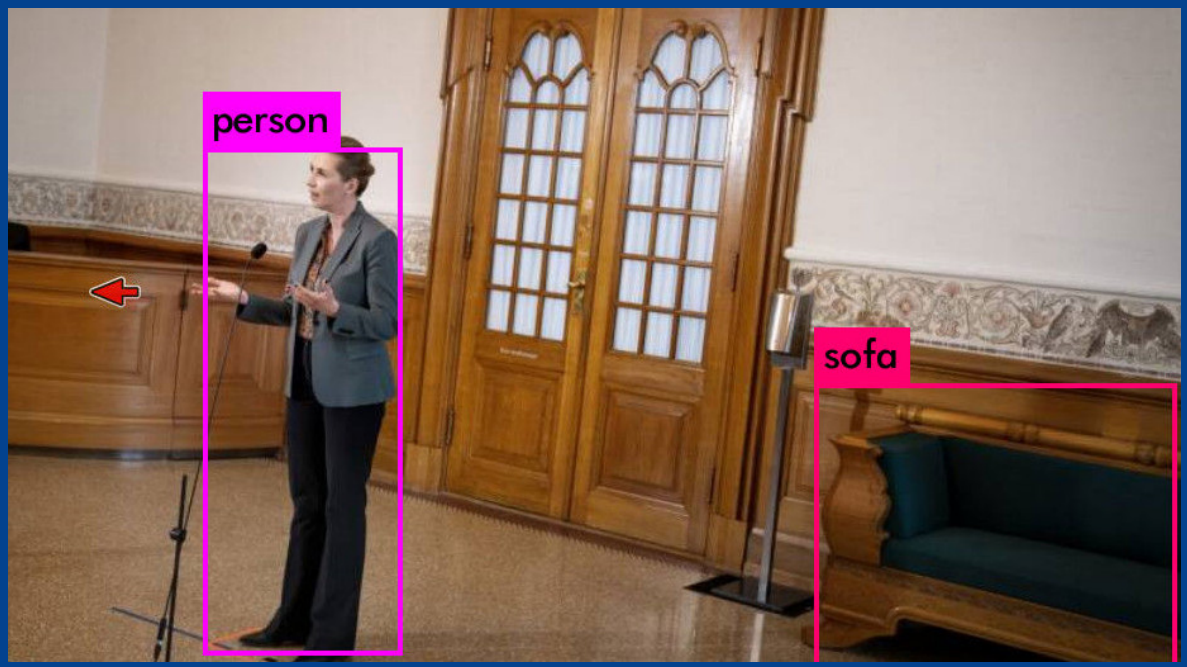
CONVOLUTIONAL NEURAL NETWORKS



Deep-learning (DL)

Artificial Intelligence:

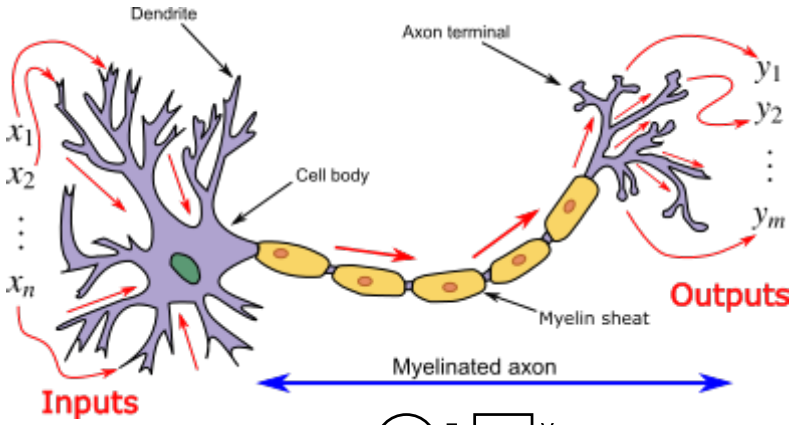
Mimicking the intelligence or behavioural pattern of humans or any other living entity.

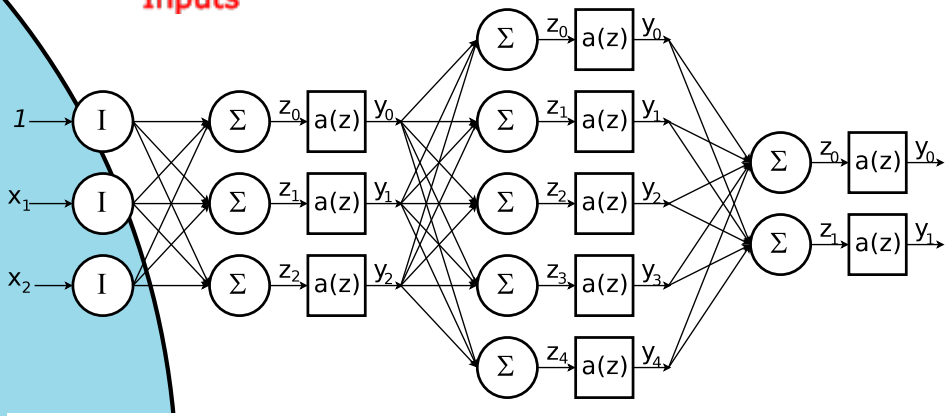
Machine Learning:

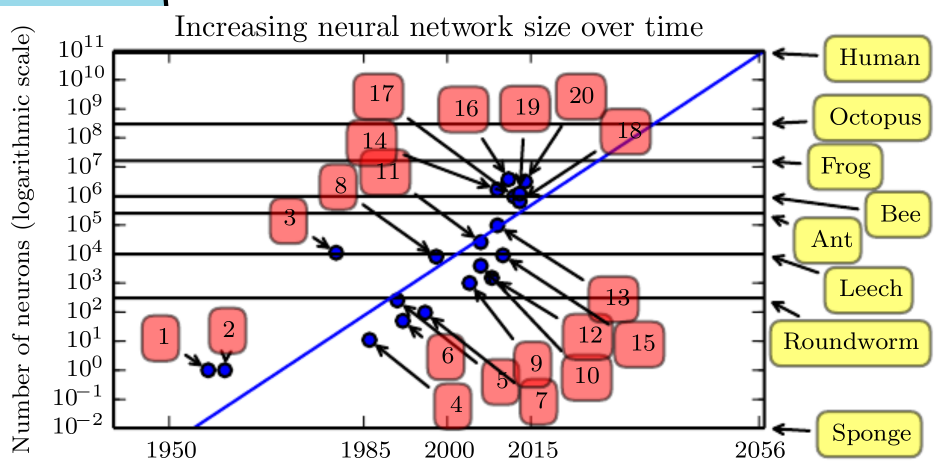
A technique by which a computer can "learn" from data, without using a complex set of different rules. This approach is mainly based on training a model from datasets.

Deep Learning:

A technique to perform machine learning inspired by our brain's own network of neurons.







Definition of DL=??

Varroa mite detector—with a CNN somewhere in the pipeline

A computer vision system to monitor the infestation level of *Varroa destructor* in a honeybee colony

Abstract

This paper presents a portable computer vision system, that is able to monitor the infestation level of the *Varroa destructor* mite in a beehive by recording a video sequence of live honeybees *Apis mellifera* for 5-20 minutes. A video monitoring unit with multispectral illumination and camera was designed to be placed in front of the beehive, where bees from a selected frame were shaken off. Subsequently, a computer vision algorithm (denoted as the *Infestation Level Estimator*) based on deep learning analysis of the video stream counted the number of honeybees and found the position of identified varroa mites. In this paper, the design and the algorithm that were used to determine the number of bees and mites are presented. Based on a video sequence with 1,775 bees and 98 visual mites, the algorithm measured the infestation level to 5.80% compared to a ground truth of 5.52% The algorithm had a high F_1-score accuracy for counting bees (0.97), while the F_1-score for detecting varroa mites was lower (0.91). The latter was due to misperdictions, which can be resolved by improving both the trained varroa classifier and the mechanical setup. Overall, the proposed computer vision system and algorithm showed a promising results in nondestructive and automatic monitoring of infestation levels in honeybee colonies and should be considered as an alternative to traditional methods, which require the killing of bees.

Keywords: Computer Vision, Deep Learning, *Varroa destructor*, *Apis mellifera*, Multi-spectral Illumination
2018 MSC: 00-01, 99-00

1. Introduction

Honeybees, *Apis mellifera*, are important in the pollination of plants and crops [1, 2]. The ectoparasitic mite *Varroa destructor* has been identified as a main driver for mortality of honeybees and particularly in honeybee colonies [3, 4], due to virus transmission [5, 6]. Beehives must be inspected for the infestation level of mites to provide the needed treatment before the damage threshold level is reached [7]. Due to the exponential growth rate of the mites and the difficulties in detecting low infection levels, optimal timing of varroa treatment is a challenge for many beekeepers [8]. A variety of methods have been developed including collecting a few hundred bees with mites and washing them with detergent or ethanol to detach the mites, passing the suspension through a sieve to determine the infestation level, or de-lodging the mites with powdered sugar [9]. These methods are the ones most commonly used to monitor the infestation level of honeybee colonies today. Ideally, a sample of 300 bees should be used for comparison between colonies as shown by Lee et al. [10]. The disadvantages of these methods are that the samples of bees and mites are killed and that it is a time consuming operation to wash, separate and count the number of bees and mites. In addition, we observed that in practice, the number of bees is not actually counted, but rather estimated based on volume or weight, which may lead to inaccurate measurements.

In this paper, we describe a new method for auto-

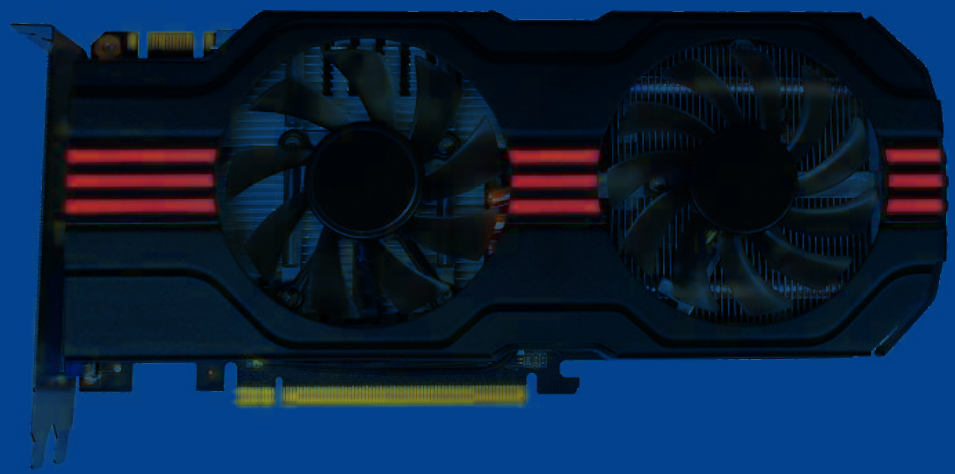
HARDWARE FOR MACHINE LEARNING



Hardware for Machine Learning

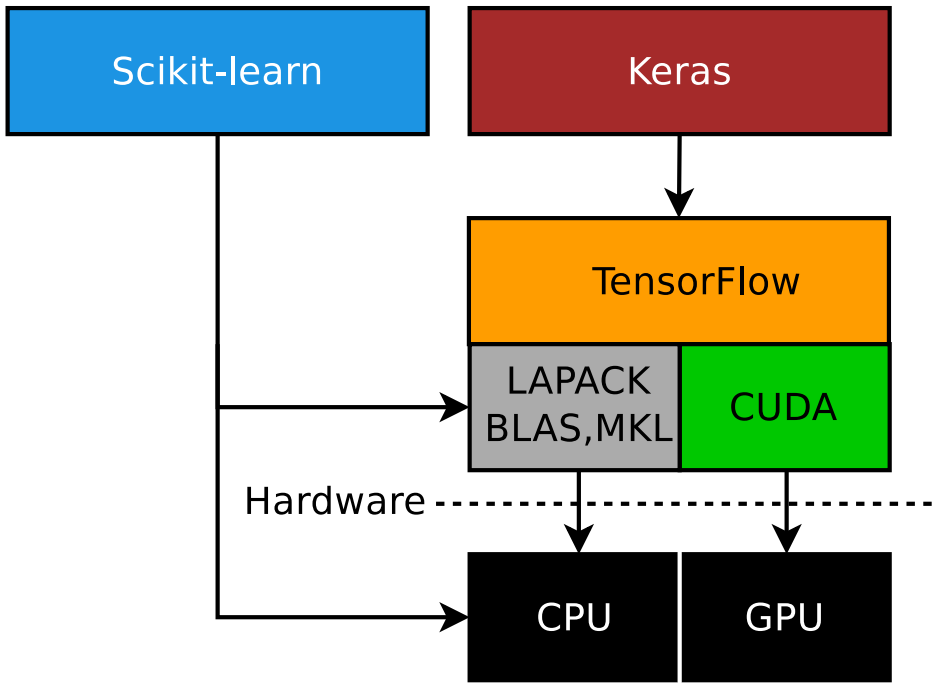
Methods and Terminology (SKIP most except μ, η)

Objective:

Why optimize using 'application specific' hardware?

- Effectiveness:
  - cost of purchasing/operating systems,
    μ=FLOPS/$
    η=FLOPS/Watt
  - cut-down developer waiting time,
  - make modelling iterations fast (say minutes).
- Big-data:
  - enable training on x-large data.
- Real-time constraints:
  - inference (on visual data)
    in real-time,
  - low-power constraints.

RESUMÉ: Keras and Tensorflow

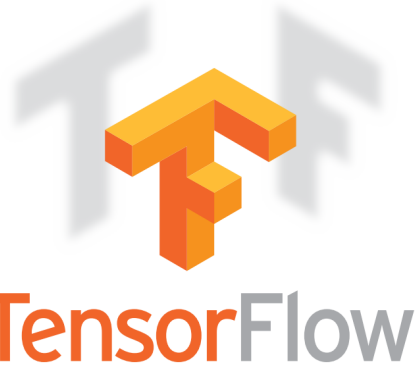


GP-GPU: General-Purpose Graphics Processing Unit...or just **GPU**.

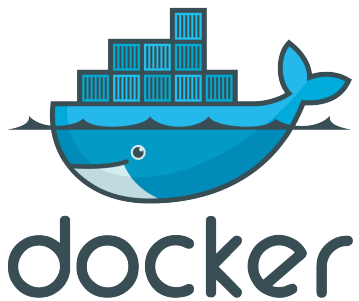
CUDA: Compute Unified Device Architecture, API for SIMD/SIMT on GPU,

CPUs

Build Tensorflow from source (SKIP)



- for specific architecture, say ARM,
- or for HPC optimization for all CPU feature



```

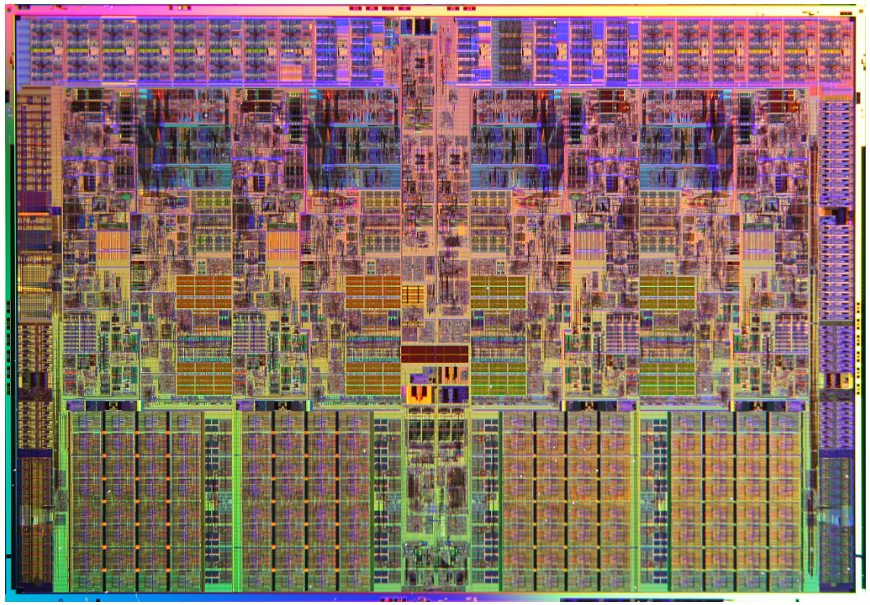
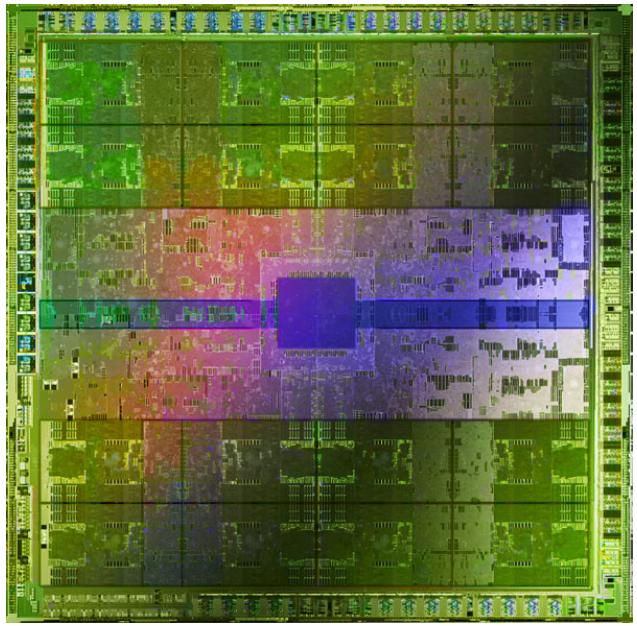
CPUs vs GPUs



Nehalem CPU
die size: $\sim$700 mm^2
transistors: $\sim 2.3 \cdot 10^9$



Fermi GPU
die size: 520 mm^2
transistors: $\sim 3 \cdot 10^9$

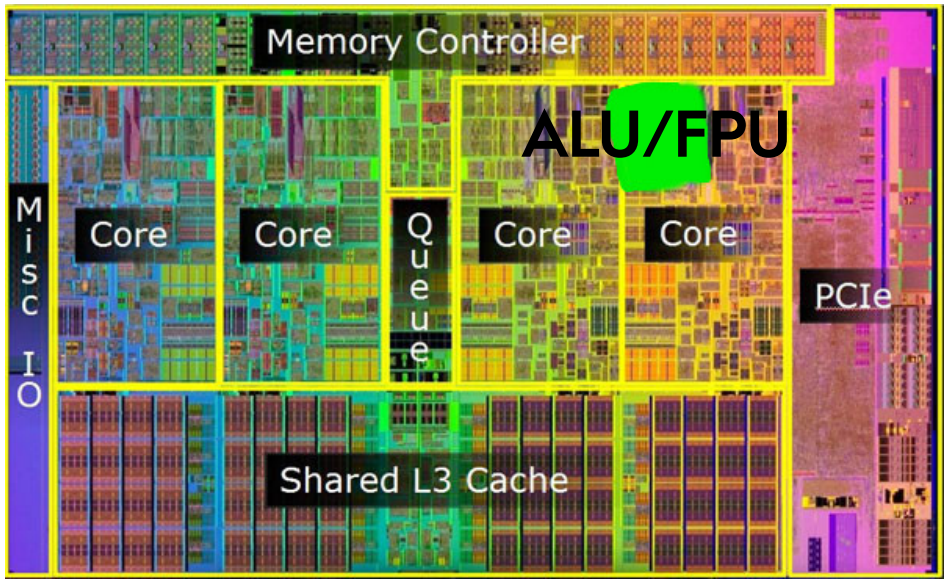
Nvidia arch. transistor counts	
Pascal	$\sim 15 \cdot 10^9$
Turing	$\sim 19 \cdot 10^9$
Volta	$\sim 21 \cdot 10^9$
Ampere	$\sim 28 \cdot 10^9$ (GPU 3090, 8nm)

CPUs vs GPUs

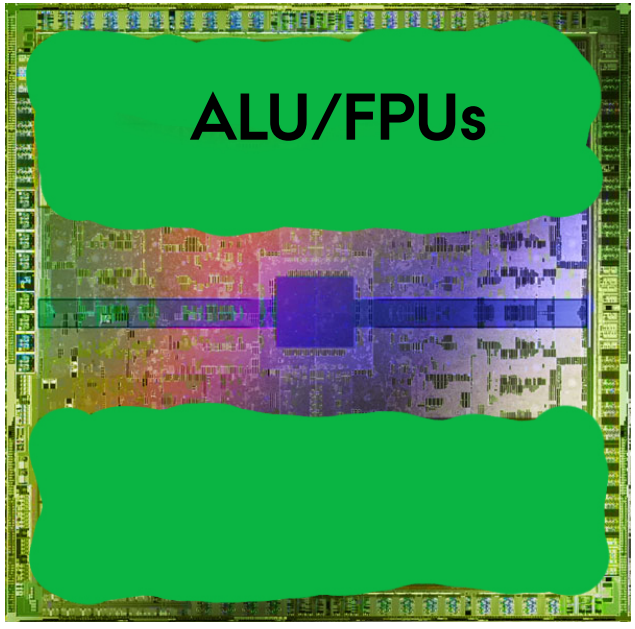
So many transistors, but how many for the ALUs/FPUs?

What makes GPUs such excellent HW for Machine Learning?

ALU: Arithmetic logic unit
FPU: Floating-point unit
Memory Controller: six controllers on GPU,
CPU: lots of speculative execution; waste of transistors.



CPU (type?)
with one ALU/FPU marked



Fermi GPU
ALUs/FPUs all over

GPUs

Fundamental Problems with the GPUs Hardware (SKIP most, except WARP)

GPUs had several *Achilles heels* related to its hardware, many of them addressed in the latest Vola V100 architecture:

- coding problems graphically, now CUDA,
- no STACK, now added,
- no CACHE (or Texture only), now both L_1 and L_2 cache,
- distinct GPU memory, now UNIFIED memory,
- SIMT WARP-bunch of 32-threads, now true SIMD,
